copley M3 3-Axis Module EtherCAT

Servo Motor Control Modes

- Cyclic Synchronous Position-Velocity-Torque (CSP, CSV, CST)
- Profile Position-Velocity-Torque, Interpolated Position, Homing
- Indexer, Point-to-Point, PVT
- Camming, Gearing
- Position, Velocity, Torque

Stepper Motor Control Modes

- Cyclic Synchronous Position (CSP)
- Profile Position-Velocity-Torque, Interpolated Position, Homing
- Position/Velocity/Torque (Servo Mode)
- Position (Microstepping)
- Indexer, Point-to-Point, PVT
- Camming, Gearing

Command Interface

- CANopen application protocol over EtherCAT (CoE)
- ASCII and discrete I/O
- Stepper commands
- ±10V position/velocity/torque
- PWM velocity/torque command
- Master encoder (Gearing/Camming)

Communications

- EtherCAT
- RS-232

Feedback

- Digital quad A/B/X encoder
- Absolute encoders
- Sin/Cos encoder
- Digital Halls

I/O Digital

- 19 HS inputs
- 3 MOSFET outputs
- 6 CMOS HS outputs

I/O Analog

• 3 ±10V inputs

I/O SPI

- 1 HS input
- 3 CMOS HS outputs

Dimensions: mm [in]

• 101.6 x 85.1 x 21 [4.0 x 3.35 x 0.80]

DESCRIPTION

The *ME3* is a 3-axis, high-performance, DC powered drive for position, velocity, and torque control of servo and stepper motors via EtherCAT. Using advanced FPGA technology, the *ME3* provides a significant reduction in the cost per node in multi-axis EtherCAT systems.

Each of the three axes in the *ME3* operate as *EtherCAT* axes under DSP-402 for motion control devices. Supported modes include: Cyclic Synchronous Position/Velocity/Torque, Profile Position-Velocity, Interpolated Position Mode (PVT), and Homing.

Servo mode of steppers allows EtherCAT or digital PWM control of position/ velocity/torque. In microstepping mode stepper command pulses and master encoder for camming or gearing is supported.

Model	Ic	Ip	Vdc
ME3-090-10	5	10	14~90

Nineteen high-speed digital inputs with programmable functions are provided. There are six CMOS high-speed outputs. Three MOSFET outputs that are 24V compatible can power motor brakes.

An SPI port is provided with one high-speed input and three high-speed digital outputs. If not used for SPI, the input and outputs are programmable for other functions.

An RS-232 serial port provides a connection to Copley's CME2 software for commissioning, firmware upgrading, and saving configurations to flash memory. The EtherCAT port is optically isolated.

Drive power is transformer-isolated DC from regulated or unregulated power supplies. An AuxHV input is provided for "keep-alive" operation permitting the drive power stage to be completely powered down without losing position information, or communications with the control system.

ME3 (É

CME2 SOFTWARE

Drive setup is fast and easy using *CME 2* software. All of the operations needed to configure the drive are accessible through this powerful and intuitive program. Auto-phasing of brushless motor Hall sensors and phase wires eliminates "wire and try". Connections are made once and *CME 2* does the rest thereafter. Encoder wire swapping to establish the direction of positive motion is eliminated. Motor data can be saved as .CCM files. Drive data is saved as .CCX files that contain all drive settings plus motor data. This eases system management as files can be cross-referenced to drives. Once a drive configuration has been completed systems can be replicated easily with the same setup and performance.

RS-232 COMMUNICATIONS

The ME3 is configured via a three-wire, full-duplex RS-232 port that operates as a DTE from 9,600 to 115,200 Baud. CME 2 software communicates with the drive over this link for commissioning and adjustments. When operating as a stand-alone drive that takes command inputs from an external controller, CME 2 is used for configuration. When operated as a EtherCAT node, CME 2 is used for programming before installation in an EtherCAT network.

CME2 -> TOOLS -> COMMUNICATIONS WIZARD

ETHERCAT COMMUNICATIONS

EtherCAT is the open, real-time Ethernet network developed by Beckhoff based on the widely used 100BASE-TX cabling system. EtherCAT enables high-speed control of multiple axes while maintaining tight synchronization of clocks in the nodes. Data protocol is CAN application protocol over EtherCAT (CoE) based on DSP-402 for motion control devices. More information on EtherCAT can be found on this web-site: http://ethercat.org/default.htm

ETHERCAT CONNECTIONS

CME2 -> Basic Setup -> Operating Mode Options

Command Source: CAN over EtherCat

Ŧ

ETHERCAT DEVICE ID (STATION ALIAS) SWITCHES

The SPI port takes in the 8 signals from the two BCD encoded switches that set the EtherCAT Device ID and controls the LEDs on the EtherCAT port connectors. The graphic below shows the circuit for reading the EtherCAT Device ID switches. The 74HC165 works as a parallel-in/serial-out device. The 10k pull-down resistors pull the shift register inputs to ground when the ME3 is initializing. In the graphics below, the values of S1 are 16~255 and of S2 are 0~15. Together they provide Device ID range of 0~255.

ETHERCAT 3-AXIS AND THE OBJECT DICTIONARY

Single-axis EtherCAT devices use objects in the range of 0x6000 to 0x67FF for standardized data that are read or written via the network as defined in CAN-CiA document CiA 301 *CANopen Application Protocol and Communication Profile.* The ME3 appears as a single slave node on an EtherCAT network that contains three logical devices: Axis A, B, and C. The standardized data objects for each is located in two sections of the object dictionary: Axis A = 0x6000 to 0x67FF (the same range as single-axis devices such as the BEL model) Axis B = 0x6800 to 0x6FFF Axis C - 0x7000 to 0x77FF Axis B objects correspond exactly to the objects for Axis A and can be addressed easily by adding 0x800 to

the index of an Axis A object. And Axis C object indexes are the same as Axis A objects + 0x1000. E.g. Mode of Operation for Axis A is 0x6060, for Axis B is 0x6860, and for Axis C is 0x7060

DIGITAL COMMAND INPUTS

Digital commands are single-ended format and should be sourced from devices with active pull-up and pull-down to take advantage of the high-speed inputs. The active edge (rising or falling) is programmable for the Pulse/Dir and CU/CD formats.

INPUTS

DIGITAL INPUTS

ME3 has 19 high-speed digital inputs, all of which have programmable functions.

They are compatible with 5V logic and have 100 ns (47 ns for IN19) R/C filters when driven by devices with active pull-up/pull-down outputs.

- Programmable functions of the digital inputs include:
- Drive Enable
- Positive Limit switch
- Negative Limit switch
- Digital Command Inputs
- Home switch
- Drive Reset
- Motion abort

0014~9	LO	Vout <= 0.8 Vdc

SPI PORT

This graphic shows all of the SPI port outputs and input together. The connections shown are those used on the ME3 Development Kit as an example of the port's usage for inputs and outputs.

HI/LO DEFINITIONS: OUTPUTS

Input	State	Condition	
[OUT7~9]	HI	Vout >= 2.2 Vdc	
	LO	Vout <= 0.8 Vdc	

SIGNALS & PINS

Output	P2 Pin	SPI Signals
[OUT7]	49	SPI EN1
[OUT8]	50	SPI Clock
[OUT9]	51	SPI MOSI
[IN19]	52	SPI MISO

If these signals are not used for the SPI port , they are programmable for other functions.

FEEDBACK CONNECTIONS

Motor connections consist of: phases, Halls, encoder, thermal sensor, and brake. The phase connections carry the drive output currents that drive the motor to produce motion. The Hall signals are three digital signals that give absolute position feedback within an electrical commutation cycle of brushless motors. Encoder signals give position feedback and are used for velocity and position modes, as well as sinusoidal commutation. A thermal sensor that indicates motor overtemperature is used to shut down the drive to protect the motor. A brake can provide a fail-safe way to prevent movement of the motor when the drive is shut-down or disabled.

QUAD A/B INCREMENTAL ENCODER WITH FAULT PROTECTION (PRIMARY FEEDBACK ONLY)

Encoders with differential line-driver outputs provide incremental position feedback via the A/B signals and the optional index signal (X) gives a once per revolution position mark. The MAX14891 receiver has differential inputs with fault protections for the following conditions:

Short-circuits line-line: This produces a near-zero voltage between A & /A, B & /B, and X & /X which is below the differential fault threshold.

Open-circuit condition: A 121Ω terminator resistor will pull the inputs together if either side (or both) is open. This will produce the same fault condition as a short-circuit across the inputs.

Low differential voltage detection: This is possible with very long cable runs and a fault will occur if the differential input voltage is < 200mV.

 $\pm 25kV$ ESD protection: The MAX14891 has protection against high-voltage discharges using the Human Body Model.

Extended common-mode range: A fault occurs if a single input voltage is outside of the range of -18.5V to +18.5V

If encoder fault detection is selected (CME2 main page, Configure Faults block, Feedback Error) and an encoder with no index is used, then the X and /X inputs must be wired as shown below to prevent the unused index input from generating an error for *low differential voltage detection*.

PANASONIC INCREMENTAL A ENCODER

This is a "wire-saving" incremental encoder that sends serial data on a two-wire interface in the same fashion as an absolute encoder.

SSI ABSOLUTE ENCODER

The SSI (Synchronous Serial Interface) is an interface used to connect an absolute position encoder to a motion controller or control system. The Accelnet drive provides a train of clock signals in differential format (Clk, /Clk) to the encoder which initiates the transmission of the position data on the subsequent clock pulses. The polling of the encoder data occurs at the current loop frequency (16 kHz). The number of encoder data bits and counts per motor revolution are programmable. Data from the encoder in differential format (Dat, /Dat) MSB first. Binary or Gray encoding is selectable. When the LSB goes high and a dwell time has elapsed, data is ready to be read again.

MOTOR CONNECTIONS

STEPPER MOTORS

The drive outputs are two H-bridge PWM inverters that convert the DC bus voltage (+HV) into sinusoidal voltage waveforms that drive the motor phase-coils. Cable should be sized for the continuous current rating of the drive. Motor cabling should use twisted, shielded conductors for CE compliance, and to minimize PWM noise coupling into other circuits. The motor cable shield should connect to motor frame and the drive HV ground terminal for best results.

BRUSH MOTORS

The drive outputs are an H-bridge PWM inverter that convert the DC bus voltage (+HV) into DC voltage waveforms that drive the motor (+) & (-) terminals. Cable should be sized for the continuous current rating of the drive. Motor cabling should use twisted, shielded conductors for CE compliance, and to minimize PWM noise coupling into other circuits. The motor cable shield should connect to motor frame and the drive HV ground terminal for best results.

DIGITAL HALL SIGNALS

Hall signals are single-ended signals that provide absolute feedback within one electrical cycle of the motor. There are three of them (U, V, & W) and they may be sourced by magnetic sensors in the motor, or by encoders that have Hall tracks as part of the encoder disc. They typically operate at much lower frequencies than the motor encoder signals, and are used for commutation-initialization after startup, and for checking the motor phasing after the servo drive has switched to sinusoidal commutation.

OUTPUTS

controls

These are open-drain MOSFETs with 1 k Ω pull-up resistors in series with a diode to +5 Vdc. They can sink up to 300 mAdc from external loads operating from power supplies to +30 Vdc. The outputs are typically configured as drive fault and motor brake. Additional functions are programmable. As a drive fault output, the active level is programmable to be HI or LO when a fault occurs. As a brake output, it is programmable to be either HI or LO to release a motor brake when the drive is enabled. When driving inductive loads such as a relay, an external fly-back diode is required. A diode in the output is for driving PLC inputs that are opto-isolated and connected to +24 Vdc. The diode prevents conduction from +24 Vdc through the 1 k Ω resistor to +5 Vdc in the drive. This could turn the PLC input on, giving a false indication of the drive output state.

MOUNTING PC BOARD CONNECTORS & SIGNALS

DEVELOPMENT KIT

DESCRIPTION

The Development Kit provides mounting and connectivity for one ME3 drive. Solderless jumpers ease configuration of inputs and outputs to support their programmable functions. Switches can be jumpered to connect to digital inputs $1 \sim 19$ so that these can be toggled to simulate equipment operation. LED's provide status indication for the digital outputs, encoder A/B/X/S signals, and Hall signals. Test points are provided for these signals, too, making it easy to monitor these with an oscilloscope.

Dual EtherCAT connectors make daisy-chain connections possible so that other EtherCAT devices such as Copley's Accelnet Plus or Xenus Plus EtherCAT drives can easily be connected. Rotary switches are provided to set the EtherCAT slave Node-ID (address).

RS-232 CONNECTION

The RS-232 port is used to configure the drive for stand-alone applications, or for configuration before it is installed into an EtherCAT network. CME 2TM software communicates with the drive over this link and is then used for complete drive setup. The EtherCAT Node-ID that is set by the rotary switch can be monitored, and a Node-ID offset programmed as well.

M3 3-Axis Module EtherCAT

The RS-232 connector, J6, is a modular RJ-11 type that uses a 6-position plug, four wires of which are used for RS-232. A connector kit is available (SER-CK) that includes the modular cable, and an adaptor to interface this cable with a 9-pin RS-232 port on a computer.

The LED on J6 is for the EtherCAT network status of Axes A, B, and C and is not associated with the RS-232 port function.

ME3 (f

SER-CK SERIAL CABLE KIT

The SER-CK provides connectivity between a D-Sub 9 male connector and the RJ-11 connector J8 on the Development Kit. It includes an adapter that plugs into the COM1 (or other) port of a PC and uses common modular cable to connect to the DevKit. The connections are shown in the diagram below.

Don't forget to order a Serial Cable Kit SER-CK when placing your order for an ME3 Development Kit!

DEVELOPMENT KIT INDICATORS (LEDS)

The AMP status LEDs DS17, DS10, and DS11 at switches SW1, 7, and 13 show the operational state of each axis of the ME3. The STAT LED on J6 shows the state of the EtherCAT NMT (Network Management) state-machines of all axes in the drive. Details on the NMT state-machine can be found in the EtherCAT Programmers Manual, §3.1: http://www.copleycontrols.com/Motion/ pdf/EtherCATProgrammersManual.pdf

AMP LEDS

Three bi-color LEDs show the states of each axis of the ME3 by changing color, and either blinking or remaining solid. The possible color and blink combinations are:

- Drive OK and enabled. Will run in response to reference inputs or EtherCAT commands. • Green/Solid:
- Green/Slow-Blinking: Drive OK but NOT-enabled. Will change to Green/Solid when enabled.
- Positive or Negative limit switch active. Drive will only move in direction not inhibited by limit switch. • Green/Fast-Blinking:
- Red/Solid: Transient fault condition. Drive will resume operation when fault is removed.
- Red/Blinkina: Latching fault. Operation will not resume until drive is Reset.

Drive Fault conditions. Faults are programmable to be either transient or latching:

• Over or under-voltage • Motor over-temperature

- Drive over-temperature
 - Internal short circuits

- Encoder +5 Vdc fault
- Short-circuits from output to around

- Short-circuits from output to output

STAT LED

A bi-color LED on J6 give the state of the NMT (Network Management) state-machine of the drive. The state is shown by changing color, and either blinking or remaining solid. The possible color and blink combinations are: RUN (GREEN)

- Off
- Init Pre-operational • Blinking
- Single-flash Stopped
- On Operational
- ERROR (RED)
- Off
- No error
- Invalid configuration, general configuration error Blinking
- Warning limit reached Single Flash
- Double Flash Error Control Event (guard or heartbeat event) has occurred
- Triple Flash Sync message not received within the configured period
- On Bus Off, the CAN master is bus off

NETWORK STATUS LEDs

Note: Red & green led on-times do not overlap. LED color may be red, green, off, or flashing of either color.

L/A LEDS

These will blink when a cable is attached and there is activity on the network.

DEVELOPMENT KIT ETHERCAT NODE ID (ADDRESS)

On a EtherCAT network, each device must have unique, non-zero Node-ID. In the ME3 DevKit, this is provided by two 16-position rotary switches with hexadecimal encoding. These can set the Node-ID of the drive's Axis A from $0x01 \sim 0xFF$ ($1 \sim 255$ decimal). The chart shows the decimal values of the hex settings of each switch.

Example 1: Find the switch settings for decimal Node-ID 107 (0x6B):

- 1) Find the highest number under SW21 that is less than 107 and set SW21 to the hex value in the same row: 96 < 107 and 112 > 107, so SW21 = 96 = Hex 6
- 2) Subtract 96 from the desired Node-ID to get the decimal value of switch SW22 and set SW22 to the Hex value in the same row: SW22 = (107 96) = 11 = Hex B
- 3) This example will produce the following CAN addresses for the ME3: Axis A = 107 (0x6B), Axis B = 108 (0x6C), Axis C = 109 (0x6D), Axis D = 110 (0x6E)

EtherCAT NODE-ID (ADDRESS) SWITCH CONNECTIONS

This graphic shows the connections to the EtherCAT Node-ID switches and to the status LEDs for the ME3 and EtherCAT. The switches are read once after the drive is reset, or powered-on. When changing the settings of the switches, be sure to either reset the drive, or to power it off-on. Outputs [OUT7,8,9] and input [IN19] operate as an SPI (Switch & LED Interface) port which reads the settings on the EtherCAT Node-ID switches, and controls the LEDs on the serial and EtherCAT port connectors. The jumpers marked with red "X" should be removed so that SW18, or external connections to the signals do not interfere with the operation of the SPI port.

CME2 -> Amplifier -> Network Configuration

DEVELOPMENT KIT+5V POWER

The encoder +5VENC power on the feedback connectors J5~J7 is connected directly to the Ax-A, Ax-B, and Ax-C power outputs from the ME3.

The SPI port components on the DevKit that drive the LEDs and read the Node-ID (address) switches connects to the signal +5VKIT. And the +5VKIT connects to a jumper on JP1 that selects a source of the +5V power.

This can be powerd from either the Ax-A, Ax-B, and Ax-C +5V power from the ME3, or from an external +5V power supply that connects to P5-3. The default "A" position (on JP1 pins $1\sim2$) selects the external +5V power source for +5VKIT.

The default "A" position (on JP1 pins 1~2) selects the external +5V power source for +5VKIT. Moving the jumper to the B, C, or D positions (pins 3~4, 5~6, 7~8) selects the axis +5V from the ME3 as the power source for the +5VKIT. As noted below, only one jumper should be used to select the source of power for +5VKIT.

IMPORTANT: ONLY ONE SHORTING PLUG CAN BE USED ON JP1

USE OF MORE THAN ONE PLUG WILL DAMAGE 5V POWER SUPPLIES IN THE ME3

THE POSITION OF THE JUMPER AT JP1-B IS THE DEFAULT THIS WILL POWER THE ON-BOARD CIRCUITS FROM AN ENCODER +5V OUTPUT

DEVELOPMENT KIT OUTPUTS

MOSFET OUTPUTS

There are three MOSFET outputs that can drive controller logic inputs or relays. If relays are driven, then flyback diodes must be connected across their terminals to clamp overvoltages that occur when the inductance of the relay coil is suddenly turned off. LED indicators connected to the outputs will be ON when the output is MOSFET is ON and the output voltage will be near OV. Outputs 1,2, & 3 are MOSFET types that sink current when ON, and appear as open-circuit when OFF. When these outputs are ON a red LED is turned on. When the outputs are OFF, the red LED is off. The green LED is not used on these outputs.

LOGIC OUTPUTS

Outputs $4 \sim 9$ are CMOS types that pull up to 5V or down to ground. When these outputs go high it turns on the green LED. When they are low, the red LED is turned on.

DEVELOPMENT KIT LOGIC INPUTS & SWITCHES

The Development Kit has jumpers that can connect the ME3 digital inputs to switches on the kit, or to the Control connector J7. As delivered, all of these jumpers are installed as shown. If connecting to external devices that actively control the level of an input, it is desirable to disconnect the switch which could short the input to ground.

For example, if [IN1] is connected to an external device for the Enable function, then jumper JP5A should be removed to take the switch SW1 out of the circuit. The figure below shows these connections.
