DESCRIPTION

The XM2 Xenus Plus 2-Axis MACRO is a high-performance, AC powered drive for torque and velocity control of brushless and brush motors via MACRO (Motion And Control Ring Optical). MACRO is a high bandwidth, nonproprietary fiber optic or wired field bus protocol for machine control networks. Connections to a MACRO ring are via SC-type fiber optic connectors. MACRO address selection is via two rotary switches for Master and Node addresses.

The XM2 Xenus Plus 2-Axis MACRO set new levels of performance, connectivity, and flexibility via the MACRO interface. A wide range of absolute interfaces are built-in including EnDat, SSI, BiSS, and Absolute A.

High resolution A/D converters ensure optimal current loop performance. Both isolated and high-speed non-isolated I/O are provided. For safety critical applications, redundant power stage enable inputs (STO) can be employed. In addition to the MACRO interface, torque and velocity control is also supported via an analog input with a ± 10 Vdc range.

Note! When you see this marker, it's for hot tips or best practices that will help you get the best results when using Copley Controls products.

MACRO COMMUNICATIONS

MACRO (Motion And Control Ring Optical) is a non-proprietary communications network that uses optical fibre or copper cabling and supports bit-rates up to 125 Mb/sec. The Xenus Plus MACRO (XM2) uses the optical fibre interface and operates typically as a torque drive. Velocity drive mode is also supported

More information on MACRO can be found on the organization web-site: http://www.macro.org/index.html

MACRO CONNECTIONS

Dual SC sockets accept standard optical fiber. The IN port connects to a master, or to the OUT port of a device that is 'upstream', between the XM2 and the master. The OUT port connects to 'downstream' nodes. If XM2 is the last node on a network, only the IN port is used. No terminator is required on the OUT port. 17: MACRO PORT

Duplex type SC optical fiber connector

MACRO ADDRESS

A PMAC card can hold up to four MACRO IC's each of which is a master on a MACRO ring. Each master IC can address 16 stations (nodes, slaves) enabling the addressing of up to 64 devices on a ring. Of these, 32 can be motion devices such as XM2.

A node address is an 8-bit value with bits 7~4 addressing the master IC and bits 3~0 addressing the slave. Switch S1 is set to select the master IC to which the Xenus will be linked. The four possible values for this setting are 0,1,2, and 3.

As a MACRO station or node the XM2 has eight available addresses as a motion control device. These are 0,1,4,5,8,9,12, & 13. Addresses 2,3,6,7,10, & 11 are for I/O stations and addresses 14 & 15 are reserved. The table shows the available selections for S2. Boxes The switch positions are numbered in hexadecimal. The chart shows these positions with the

slave address shown in decimal.

Example: Configure the XM2 as node 36 (0x24)

The XM2 will be node 4 controlled by master IC 2 on the PMAC

S1 = 2 (Master IC 2)

S2 = 4 (Slave address)

The S1 settings are in multiples of 16 (2^4) , so 2 X 16 = 32. The S2 settings are read directly equal 4. This produces the node address of $2 \times 16 + 4 = 36$.

COMMUNICATIONS: RS-232 SERIAL

RS-232 COMMUNICATIONS

XM2 is configured via a three-wire, full-duplex DTE RS-232 port that operates from 9600 to 115,200 Baud, 8 bits, no parity, and one stop bit. Signal format is full-duplex, 3-wire, DTE using RxD, TxD, and Gnd. Connections to the XM2 RS-232 port are through J7, an RJ-11 connector. The XM2 Serial Cable Kit (SER-CK) contains a modular cable, and an adapter that connects to a 9-pin, Sub-D serial port connector (COM1, COM2, etc.) on PC's and compatibles.

SER-CK SERIAL CABLE KIT

The SER-CK provides connectivity between a D-Sub 9 male connector and the RJ-11 connector on the XM2. It includes an adapter that plugs into the COM1 (or other) port of a PC and uses common modular cable to connect to the XM2. The connections are shown in the diagram below.

Don't forget to order a Serial Cable Kit SER-CK when placing your order for an XM2!

ASCII COMMUNICATION PROTOCOL

ASCII COMMUNICATIONS

The Copley ASCII Interface is a set of ASCII format commands that can be used to operate these drives over an RS-232 serial connection. For instance, after basic amplifier configuration values have been programmed using CME 2, a control program can use the ASCII Interface to:

- Enable the amplifier in Programmed Position mode.
- Home the axis.
- Issue a series of move commands while monitoring position, velocity, and other run-time variables.

The Baud rate defaults to 9,600 after power-on or reset and is programmable up to 115,200 thereafter. After power-on, reset, or transmission of a Break character, the Baud rate will be 9,600. Once communication has been established at this speed, the Baud rate can be changed to a higher rate (19,200, 57,600, 115,200). ASCII parameter 0x90 holds the Baud rate data. To set the rate to 115,200 enter this line from a terminal:

s r0x90 115200 <enter>

Then, change the Baud rate in the computer/controller to the new number and communicate at that rate.

Additional information can be found in the ASCII Programmers Guide on the Copley website: <u>http://www.copleycontrols.com/Motion/pdf/ASCII ProgrammersGuide.pdf</u>

SAFE TORQUE OFF (STO)

DESCRIPTION

The XM2 provides the Safe Torque Off (STO) function as defined in IEC 61800-5-2. Three opto-couplers are provided which, when de-energized, prevent the upper and lower devices in the PWM outputs from being operated by the digital control core. This provides a positive OFF capability that cannot be overridden by the control firmware, or associated hardware components. When the opto-couplers are activated (current is flowing in the input diodes), the control core will be able to control the on/off state of the PWM outputs.

Refer to the Xenus Plus Dual-Axis STO User Manual

INSTALLATION

The information provided in the Xenus Plus Dual-Axis STO User Manual must be considered for any application using the XM2 drive's STO feature. Failure to heed this warning can cause equipment damage, injury, or death.

STO BYPASS (MUTING) In order for the PWM outputs of the XM2 to be activated, current must be flowing through all of the opto-couplers that are connected to the STO-1 and STO-2 terminals of J6, and the drive must be in an ENABLED state. When the opto-couplers are OFF, the drive is in a Safe Torque Off (STO) state and the PWM outputs cannot be activated by the control core to drive a motor. This diagram shows connections that will energize all of the opto-couplers from an internal current-source. When this is done the STO feature is overridden and control of the output PWM stage is under control of the digital control core.

If not using the STO feature, these connections must be made in order for the XM2 to be enabled.

STO MUTING (BYPASS) CONNECTIONS Bypass Plug Connections Jumper pins: 2-4, 3-5, 6-8, 7-9 * Note: STO applies to Axis-A AND Axis-B V in PWM Signals Xenus Plus Dual-Axis FN Voltage J6 Buffer Regulato Upper IGBT Gate Drive Current must flow through all of the opto-STO-1(+) 2 couplers before the XM2 +HV can be enabled STO-1(-) PWM Outputs * STO bypass connections on the XM2 and Xenus STO-2(+) 4 XEL/XPL/XML models are different. If both drives are installed in the same cabinet, the diode STO-2(-) should be wired as shown to prevent damage that could occur if the STO bypass connectors are installed on the wrong drive. The diode is not required for STO bypass on the XM2 and can be STO-1(+) +VI Lower IGBT Gate Drive 6 replaced by a wire between pins 7 and 9. STO-1(-) STO-24V (8) ------STO-GND 9 * XM2 and XEL-XPL STO bypass connections are different. The diode shown should be used if XM2 and XEL-XPL drives are used on the same equipment. Otherwise, the diode may be replaced by a jumper. XM2 STO bypass connectors are not compatible with XEL-XPL drives. 4 Frame Ground 1 A

* PROGRAMMABLE PULL UP/DOWN

The input resistor of these inputs is programmable to pull-up to +5V or pull-down to 0V. Pull-up is the default and works with current-sinking outputs from a controller. Pull-down works with current-sourcing outputs, typically PLC's that drive grounded loads. Six of the inputs have individually settable PU/PD. The other four have PU/PD control for pairs of inputs.

SINGLE-ENDED/DIFFERENTIAL DIGITAL INPUTS [IN2~5,12~15]

These inputs have all the programmable functions of the GP inputs plus these additional functions which can be configured as single-ended (SE) or differential (DIFF):

- PWM 50%, PWM & Direction for Velocity or Current modes
- Pulse/Direction, CU/CD, or A/B Quad encoder inputs for Position or Camming modes

SINGLE-ENDED 12 Vdc max

12 Vdc max

DIFFERENTIAL

PLC outputs are frequently current-sourcing from 24V for driving grounded loads. PC based digital controllers commonly use NPN or current-sinking outputs. Set the Xenus inputs to pull-down to ground for current-sourcing connections, and to pull-up to 5V for current-sinking connections.

OPTO-ISOLATED INPUTS: IN6, IN7, IN8, IN9, IN16, IN17, IN18, IN19

These inputs have all the programmable functions of the GP inputs plus opto-isolation. There are two groups of four inputs, each with a common terminal. Grounding the common terminal configures the inputs to work with current-sourcing outputs from controllers like PLC's. When the common terminal is connected to +24V, the inputs will be activated by current-sinking devices such as NPN transistors or N-channel MOSFETs. The minimum ON threshold of the inputs is ± 15 Vdc.

IN THE GRAPHICS BELOW, "24V" IS FOR CONNECTIONS TO CURRENT-SOURCING OUTPUTS AND "GND" IS FOR CURRENT-SINKING OUTPUTS ON THE CONTROL SYSTEM

These inputs work with current-sourcing OR current-sinking connections. Connect the COMM to controller ground/common for current-sourcing connections and to +24V for currentsinking connections.

The 24V power shown in these connection diagrams does not have to be connected to the logic power supply for the drive, and is commonly provided in the control system to power relays and other devices.

ANALOG INPUTS

The analog inputs have a ± 10 Vdc range at 14-bit resolution As reference inputs they can take position/velocity/torque commands from a controller. If not used as command inputs, they can be used as general-purpose analog inputs.

Output	Data	Notes
Voltage Range	Max	+30 Vdc
Output Current	Ids	1.0 Adc

HI/LO DEFINITIONS: OUTPUTS

Input	State	Condition
BRK-A,B	HI	Output transistor is OFF Brake is un-powered and locks motor Motor cannot move Brake state is Active
OUT6,7	LO	Output transistor is ON Brake is powered, releasing motor Motor is free to move Brake state is NOT-Active

CME2 Default Setting for Brake Outputs [OUT6,7] is "Brake - Active ${\rm HI}^{\prime\prime}$

Active = Brake is holding motor shaft (i.e. the *Brake is Active*) Motor cannot move No current flows in coil of brake CME2 I/O Line States shows Output 6 or 7 as HI BRK Output voltage is HI (24V), MOSFET is OFF Servo drive output current is zero Servo drive is disabled, PWM outputs are off

Inactive = Brake is not holding motor shaft (i.e. the *Brake is Inactive*) Motor can move Current flows in coil of brake CME2 I/O Line States shows Output 6 or 7 as LO BRK output voltage is LO (~0V), MOSFET is ON Servo drive is enabled, PWM outputs are on

Servo drive output current is flowing

Earthing connections for power supplies should be as close as possible to elimimate potential differences between power supply 0V terminals.

There should be only one conductor in each position of the J5 connector. If brakes are to be wired directly to J5 for their 24V power, use a double wire ferrule for J5-4. Information for ferrules can be found on page 27.

*

The brake circuits are optically isolated from all drive circuits and frame ground.

CONNECTIONS

Pin	Signal
5	+24V
4	+24V
3	A Brk [OUT6]
2	B Brk [OUT7]
1	24V Return

This diagram shows the connections to the drive that share a common ground in the driver. If the brake 24V power supply is separate from the DC supply powering the drive, it is important that it connects to an earth or common grounding point with the HV power supply.

MOTOR CONNECTIONS: ENCODERS

Motor connections are of three types: phase, feedback, and thermal sensor. The phase connections carry the drive output currents that drive the motor to produce motion. A thermal sensor that indicates motor overtemperature is used to shut down the drive to protect the motor. Feedback can be digital quad A/B encoder, analog sin/cos encoder, or digital Halls, depending on the version of the drive.

QUAD A/B ENCODER WITH FAULT PROTECTION

Encoders with differential line-driver outputs are required (single-ended encoders are not supported) and provide incremental position feedback via the A/B signals and the optional index signal (X) gives a once per revolution position mark. The MAX3097 receiver has differential inputs with fault protections for the following conditions:

Short-circuits line-line: Open-circuit condition: This produces a near-zero voltage between A & /A which is below the differential fault threshold. The 121Ω terminator resistor will pull the inputs together if either side (or both) is open. This will produce the same fault condition as a short-circuit across the inputs.

Low differential voltage detection: ±15kV ESD protection:

This is possible with very long cable runs and a fault will occur if the differential input voltage is < 200mV. The 3097E has protection against high-voltage discharges using the Human Body Model. A fault occurs if the input common-mode voltage is outside of the range of -10V to +13.2V

Extended common-mode range: A fai

CONNECTIONS WITH A/B/X ENCODER

CONNECTIONS WITH NO INDEX SIGNAL

SHIELDED CABLE CONNECTIONS

Double-shielded cable is recommended for analog sin/cos encoders. The outer shield connects to the motor and drive frames. The inner shield(s) should only connect to the Signal Ground at the drive. The inner shields shown here are for individually shielded twisted-pair cables. If the inner shield is a single one, it connects to Signal Ground at the drive.

The inner shield should have no connection at the motor, or the the outer shield. Double-shielding is used less frequently for digital encoders, but the connections are shown here and on following pages for completeness.

ANALOG SIN/COS INCREMENTAL ENCODER

The sin/cos/idx inputs are differential with 121 Ω terminating resistors and accept 1 Vp-p signals in the format used by incremental encoders with analog outputs, or with ServoTube motors.

MOTOR CONNECTIONS: ABSOLUTE ENCODERS

SSI ABSOLUTE ENCODER

The SSI (Synchronous Serial Interface) is an interface used to connect an absolute position encoder to a motion controller or control system. The XEL drive provides a train of clock signals in differential format to the encoder which initiates the transmission of the position data on the subsequent clock pulses. The polling of the encoder data occurs at the current loop frequency (16 kHz). The number of encoder data bits and counts per motor revolution are programmable. The hardware bus consists of two signals: SCLK and SDATA. Data is sent in sloteytes, LSB first. The SCLK signal is only active during transfers. Data is clocked out on the falling edge and clock in on the rising edge of the Master.

BISS ABSOLUTE ENCODER

BiSS is an - Open Source - digital interface for sensors and actuators. BiSS refers to principles of well known industrial standards for Serial Synchronous Interfaces like SSI, AS-Interface® and Interbus® with additional options.

Serial Synchronous Data Communication

- Cyclic at high speed
- 2 unidirectional lines Clock and Data
 - Line delay compensation for high speed data transfer Request for data generation at slaves Safety capable: CRC, Errors, Warnings
 - Bus capability incl. actuators

Bidirectional

BISS B-protocol: Mode choice at each cycle start BISS C-protocol: Continuous mode

ENDAT ABSOLUTE ENCODER

The EnDat interface is a Heidenhain interface that is similar to SSI in the use of clock and data signals, but which also supports analog sin/cos channels from the same encoder. The number of position data bits is programmable as is the use of sin/cos channels. Use of sin/cos incremental signals is optional in the EnDat specification.

ABSOLUTE-A ENCODER & INCREMENTAL A

The interface is a serial, half-duplex type that is electrically the same as $\mathsf{RS}\text{-}485.$

MOTOR CONNECTIONS: MOTOR, HALLS, OVERTEMP

MOTOR PHASE CONNECTIONS

The drive output is a three-phase PWM inverter that converts the DC buss voltage (+HV) into three sinusoidal voltage waveforms that drive the motor phase-coils. Cable should be sized for the continuous current rating of the motor. Motor cabling should use twisted, shielded conductors for CE compliance, and to minimize PWM noise coupling into other circuits. The motor cable shield should connect to motor frame and the drive frame ground terminal (J3,J4-1) for best results.

MOTOR SIGNALS						
Signal	J3,J4 Pin					
Mot U	4					
Mot V	3					
Mot W	2					
Shield	1					

DIGITAL HALL SIGNALS

Hall signals are single-ended signals that provide absolute feedback within one electrical cycle of the motor. There are three of them (U, V, & W) and they may be sourced by magnetic sensors in the motor, or by encoders that have Hall tracks as part of the encoder disc. They typically operate at much lower frequencies than the motor encoder signals, and are used for commutation-initialization after startup, and for checking the motor phasing after the amplifier has switched to sinusoidal commutation.

Resistance at 85°C	≤1650
Resistance at 95°C	≥3990
Resistance at 105°C	≥12000

MOTOR OVER TEMP INPUT

The 4.99k pull-up resistor works with PTC (positive temperature coefficient) thermistors that conform to BS 4999:Part 111:1987 (table below), or switches that open/close indicating a motor over-temperature condition. The active level is programmable.

MULTI-MODE ENCODER PORT

The multi-mode port can operate as primary or secondary feedback from digital quad A/B/X or absolute encoders.

FEEDBACK FROM DIGITAL QUADRATURE ENCODER When operating in position mode the multi-mode port can accept digital command signals from external encoders. These can be used to drive cam tables, or as master-encoder signals when operating in a master/ slave configuration.

MULTI-MODE ENCODER PORT: COMMAND INPUTS

AS A MASTER OR CAMMING ENCODER INPUT FROM A DIGITAL QUADRATURE ENCODER

When operating in position mode the multimode port can accept digital command signals from external encoders. These can be used to drive cam tables, or as master-encoder signals when operating in a master/slave configuration.

Frame Gnd			J12	2-1

AS DIGITAL COMMAND INPUTS IN PULSE/ DIRECTION, PULSE-UP/PULSE-DOWN, OR DIGITAL QUADRATURE ENCODER FORMAT

The multi-mode port can also be used when digital command signals are in a differential format. These are the signals that typically go to single-ended inputs. But, at higher frequencies these are likely to be differential signals in which case the multi-mode port can be used.

MULTI-MODE ENCODER PORT: FEEDBACK OUTPUTS

AS BUFFERED OUTPUTS FROM A DIGITAL QUADRATURE PRIMARY ENCODER

When using a digital quadrature feedback encoder, the A/B/X signals drive the multi-mode port output buffers directly. This is useful in systems that use external controllers that also need the motor feedback encoder signals because these now come from J12, the Control connector. In addition to eliminating "Y" cabling where the motor feedback cable has to split to connect to both controller and motor, the buffered outputs reduce loading on the feedback cable that could occur if the motor encoder had to drive two differential inputs in parallel, each with it's own 121 ohm terminating resistor.

AS EMULATED QUAD A/B/X ENCODER OUTPUTS FROM AN ANALOG SIN/COS FEEDBACK ENCODER

Analog sin/cos signals are interpolated in the drive with programmable resolution. The incremental position data is then converted back into digital quadrature format which drives the multi-mode port output buffers. Some analog encoders also produce a digital index pulse which is connected directly to the port's output buffer. The result is digital quadrature A/B/X signals that can be used as feedback to an external control system.

CME2 Default Setting for Brake Outputs [OUT6,7] is "Brake - Active HI" Active = Brake is holding motor shaft (i.e. the *Brake is Active*)

 Active
 > Drake
 > Drake is Active)

 Motor cannot move
 No current flows in coil of brake

 CME2 I/O Line States shows Output 6 or 7 as HI

 BRK Output voltage is HI (24V), MOSFET is OFF

 Servo drive output current is zero

 Servo drive is disabled, PWM outputs are off

 Inactive
 = Brake is not holding motor shaft (i.e. the Brake is Inactive)

 Motor can move
 Current flows in coil of brake

 CME2 I/O Line States shows Output 6 or 7 as LO

 BRK output voltage is LO (~0V), MOSFET is ON

 Servo drive is enabled, PWM outputs are on

 Servo drive output current is flowing

MOTOR CONNECTIONS FOR DIGITAL INCREMENTAL ENCODERS

POWER & GROUNDING

DRIVE POWER SOURCES

An external +24 Vdc power supply is required, and powers an internal DC/ DC converter that supplies all the control voltages for drive operation. Use of an external supply enables MACRO communication with the drive when the mains power has been removed.

Power distribution in *XM2* is divided into three sections: +24 Vdc, signal, and high-voltage. Each is isolated from the other and all are isolated from the chassis.

EXTERNAL +24 VDC

The primary side of the DC/DC converter operates directly from the external +24Vdc supply and is isolated from other drive power sections. The Brake outputs operate in this section and are referenced to the +24Vdc return (0V). They sink current from an external load connected to the external +24Vdc power source.

INTERNAL SIGNAL POWER

The signal power section supplies power for the control circuits as well as logic inputs and outputs. Motor feedback signals such as Halls, encoder, and temperature sensor operate from this power source. All signal circuits are referenced to signal ground. This ground should connect to the control system circuit ground or common so that drive and controller inputs and output voltage levels work properly with each other.

MAINS POWER

Mains power drives the high-voltage section. It is rectified and capacitorfiltered to produce +HV which the PWM stages convert into voltages that drive either three phase brushless or DC brush motors. An internal solid-state switch together with an external power resistor provides dissipation during regeneration when the mechanical energy of the motors is converted back into electrical energy that must be dissipated before it charges the internal capacitors to an overvoltage condition. All the circuits in this section are "hot", that is, they connect directly to the mains and must be considered high-voltages and a shock hazard requiring proper insulation techniques during installation.

GROUNDING

A grounding system has three primary functions: safety, voltage-reference, and shielding. As a safety measure, the primary ground at J1-3 will carry fault-currents from the mains in the case of an internal failure or short-circuit of electronic components. Wiring to this is typically done with the green conductor with yellow stripe using the same gauge wire as that used for the mains. The pin on the drive at J1-3 is longer than the other pins on J1 giving it a first-make, last-break action so that the drive chassis is never ungrounded when the mains power is connected. This wire is a 'bonding' conductor that should connect to an earthed ground point and must not pass through any circuit interrupting devices.

All of the circuits on J1, J2, J3, and J4 are mains-connected and must never be grounded. The frame ground terminals at J1-3, J2-3, J3-1, J4-1, J6-1, J9-1, J10-1, J11-1, and J12-1 all connect to the drive chassis and are isolated from all drive internal circuits.

Signal grounding references the drive control circuits to those of the control system. These controls circuits typically have their own earth connection at some point. To eliminate ground-loops it is recommended that the drive signal ground be connected to the control system circuit ground. When this is done the drive signal voltages will be referenced to the same 0 V level as the circuits in the control system. Small currents flow between controller and drive when inputs and outputs interact. The signal ground is the path for these currents to return to their power sources in both controller and drive.

Shields on cables reduce emissions from the drive for CE compliance and protect internal circuits from interference due to external sources of electrical noise. Because of their smaller wire gauge, these should not be used as part of a safety-ground system. Motor cases can be safety-grounded either at the motor, by earthing the frame, or by grounding conductors in the motor cables that connect to J3-1 & J4-1. These cables should be of the same gauge as the other motor phase cables.

For CE compliance and operator safety, the drive heatplate should be earthed to the equipment frame. An unplated tab is provided on the heatplate (near to J1) for this connection.

POWER SECTIONS

The graphic below shows the different power sections of the Xenus Plus drive and the isolation barriers between them. Only one motor is shown but all motor PWM drivers are in the mains-connected section.

POWER, REGEN, & BRAKE CONNECTIONS

Notes:

- 1) Items marked with CE are required for standards conformance.
- 2) In the end product installation, a UL RC (Recognized Component) SPD (Surge Protective Device) type 1CA, 2CA, 3CA or a UL Listed (VZCA) SPD type 1, 2, or 3 rated 2500 V, with a minimum SCCR of 5 kA, 240 Vac, and surge voltage monitoring needs to be provided if the over-voltage category of the installation is greater than Category II. When this occurs, the purpose of the SPD is to establish an over-voltage CAT II environment for the drives.
 3) The line filter used in CE conformance testing was a Filter Concepts 3F15.
- 4) Fuses and/or circuit breakers are optional and can be selected by the user to meet local codes and/or machine construction requirements.
- 5) The internal regen resistor of the XM2 must be unplugged when using an external regen resistor. Only one regen resistor can be connected to the Regen connector J2.

Xenus^{PLUS} 2-Axis MACRO

GROUNDING & SHIELDING

Grounding for Safety

The protective earth (PE) ground at J1-3 (for both single and dual axis drives), is the electrical safety ground and is intended to carry the fault currents from the mains in the case of an internal failure or shortcircuit of electronic components. Wiring to this ground should be done using the same gauge wire as that used for the mains. This wire is a "protective bonding" conductor that should be connected to an earthed ground point and must not pass through any circuit interrupting devices. The PE ground also connects to the drive heatplate (Frame Ground, FG). Connections of the regen and motor cable shields to the FG points (J2-1, J3-1) is done to prevent the motor or regen resistor housing from becoming hazardous in the event of an insulation failure. Protective earth connections for the motor and regen resistor housings are subject to local electrical codes and must be reviewed for compliance with those codes. It is the responsibility of the end user to

ensure compliance with local electrical codes and any other applicable standards. It is strongly recommended that motor and regen resistor housings also be connected to protective earth connection points located as close to the motor and regen resistor as possible. In many applications, the machine frame is used as a primary or supplemental protective earth connection point for the motor and regen resistor housings

Grounding and Shielding for CE Compliance

These connections are the means of controlling the emission of radio frequency energy from the drive so that it does not interfere with other electronic equipment. The use of shielded cables to connect the drive to motors and feedback devices is a way of extending the chassis of the drive out to these devices so that the conductors carrying noise generated by the drive are completely enclosed by a conductive shield. The FG ground terminals provide cable shield connection points for the motor, feedback, and regen resistor cables. By connecting the shields for these devices at the drive and at the device, the connection is continuous and provides a return path for radio-frequency energy to the drive.

To further minimize electrical noise it is important to keep the connection between the drive heatplate and earth/equipment frame as short as possible. A Heatplate Grounding Screw is provided for making this connection.

Grounding for Leakage Current Requirements

The connection to the Heatplate Grounding Screw also provides a second protective earthing conductor to address the touch current requirements of IEC 61800-5-1. *Further information on this topic can be found in the Xenus Plus User Guide.*

HEATPLATE GROUNDING SCREW

Keep the chassis grounding connections short for best shielding performance

Notes:

1) Shielded cables required for CE are shown in the diagram above.

2) Line filter required for CE

Xenus^{PLUS} 2-Axis MACRO

REGENERATION

The drive has has an internal regen resistor which can handle regenerative energy that exceeds the absorption capacity of the internal bus capacitance. The internal regen resistor will be switched on when the energy shown in the table has been absorbed and the bus voltage driven up to 390 Vdc at which point the internal regen resistor will be switched to absorb the kinetic energy of the load.

ABSORPTION					
Vac	Ε				
100	155				
120	145				
200	85				
240	43				

Absorption is the energy that can be transferred to the internal capacitors during deceleration. This table shows the energy absorption in W·s for a drive operating at some typical mains voltages. The capacitor bank is 2350 uF and the energy absorption is shared with both axes. If the deceleration energy is less than the absorption capacity of the drive, then a regeneration resistor will not be used because the bus voltage will not rise enough to hit the over-voltage level that would disable the PWM outputs.

Terms:

]

D

- E Energy
 - Rotary Moment of Inertia Power

Joules, Watt·seconds kg·m² Watts

Velocity Velocity Bus Vdc HVdc Absorption Bus Active Regen Resistor Off

CALCULATING THE REGEN REPETITION FREQUENCY

Step 1: Find the energy of motion for a rotating load, for this example let it be 75 Joules:

 $E = J * \text{RPM}^2 = 75 \text{ J}$ Joules; kg·m², RPM 182

Step 2: Subtract the absorption at your mains voltage to get the energy that must be dissipated in the regen resistor. Use 240 Vac:

Step 3: Divide the regen energy by the continuous power rating of 20 Watts to get the dwell time that can dissipate the regen energy in the resistor:

Dwell Time = 32 Joules = 1.6 sec 20 Watts___

Seconds; Joules, Watts

- Step 4: Find the total regen cycle time by adding the deceleration time to the dwell time:
 - Decel Time = 1.25 sec Dwell Time = 1.60 sec Cycle Time = 2.85 sec
